EXPRESS MAILING LABEL NO.:

EU115634926US

Customer No.: 28986

RECOMBINANT TYPE II RESTRICTION ENDONUCLEASES, TO PRODUCTING THE SAME

AND RELATED ENDONUCLEASES AND Docket No.: NEB-207-US The present invention relates to a DNA fragment codes

The present acid) fragment, which fragment or related enrimenting (deoxyribonucleic acid) fragment, tun related enrimentiale messesing tun related enrimentiale messes enriched en (deoxyribonucleic acid) fragment, which tragment codes

the number of th Tor one polypeptice possessing two related enzymetic the DNA recognizes the DNA recognizes the polypeptice possessing two recognizes the polypeptice polypeptice possessing two recognizes the polypeptice polypep functions, namely an enzyme which recognizes the DNA this sequence 5, TCC (Pu) AC-3, and cleaves the phosphodiester sequence 5, TCC (Pu) AC-3, and cleaves the phosphodiester and cleaves bond between the 20th and 21st residues 3' to this the recomition sequence on this DNA strand, rion committee and recognition sequence of the recognition sequence of the recognition and recognition sequence on this DNA strand, and between the recognition sequence on this the recognition of the residues of the recognition of the residues of the recognition of the recog 5 18th and 19th residues 5, cor (Py) GGT-3, to produce a 18th complement strand 5, cor (Py) GGT-3, to produce the the complement strand in the compl the complement strand 5'-GT(Py)GGT-3' to produce a 2

the complement strand 5'-GT(Py)GGT-3' to as the MmeI

the complement strand 5'-GT(Py)GGT-3' to as the MmeI

the complement strand 5'-GT(Py)GGT-3' to produce a 2

the complement strand 5'-GT(Py)GGT-3' to produce pase 3. extension (nereinaiter referred to as the second enzymatic and a second enzymatic restriction endonuclease); the same own second restriction endonuclease); restriction endonuclease) and a second enzymatic simple same DNA sequence, as activity that recognizes the same activity that recognizes activity that recognizes the same DNA sequence, by the addition activity that recognizes this sequence by the modifies the same power of the modifies are the modified activity that recognizes the same power of the modifies the sequence. 10 of a methyl group to prevent cleavage by the Amel of a methyl group to prevent invention also relates to a endonuclease. The present invention endonuclease. The present invention also relates to a transformed host endonuclease. The present invention a transformed host vector containing the DNA fragment. vector containing the DNA fragment, and an improved process from each containing this DNA fragment, and an improved process from each containing this process from containing the process from contain containing this DNA tragment, and an improved process a containing this DNA tragment, and an improved process are transformed to producing MmeI restriction endonuclease from all restriction endonuclease from the process transformed to the process and an improved process are formed to the process and an improved process are formed to the process and an improved process are formed to the process and an improved process are formed to the process and an improved process are formed to the process and an improved process are formed to the process and an improved process are formed to the p Tor producing mmel restriction endonuclease from such a to the present invention also relates to the present invention also relates to transformed host. The present additional man for identifying additional management is a proposed for identifying additional management is a proposed for identifying additional management. 15 transformed nost. The present invention also relates to a process for identitying additional DNA tragments the same general properties as encode enzymes having the same general properties. encode enzymes naving the same general properties at the same MmeI but potentially having unique DNA recognition the amino on the use of the amino sequences. This process depends on processing processing area on the sequences. 20 sequences. This process depends on the use of this made in this acid sequence of the Manel enzyme the additional commences. acid sequence of the MmeI enzyme presented in this sequences acid sequence of the mmeI enzyme the additional sequences application; have the acid sequence of subsequently on the invention along the application; have the acid sequence of the mmeI enzyme additional sequences acid sequence of the mmeI enzyme presented in this sequences acid sequences of the mmeI enzyme presented in this sequences. application, or subsequently on the additional sequently on the invention also identified through this process. The identified through this process. Identified through this process. The identifiable identifiable relates to additional DNA fragments. relates to additional UNA tragments, of which encodes a through the process eignificant amino acid companies through the process of mificant amino acid companies through the process of mificant amino acid companies through the process of mificant amino acid companies through the process of missions of the process of the 25 through the process described, each or which encodes polypeptide having significant amino must be processed as a significant amino must be polypeptide having significant significant significant significant significant significant significant sign polypeptide naving significant amino acid sequence rhe polypeptides to the MmeI polypeptide. 30 35

```
encoded by these DNA fragments are predicted to perform
Docket No.: NEB-207-US
                                                                               encoded by these UNA tragments are predicted to per they are similar functions to MmeI. Specifically, functions to MmeI.
                                                                                             similar functions to MmeI. Specifically functions of the dual enzymatic relations of predicted to possess the dual enzymatic relations.
                                                                                                                predicted to possess the dual enzymatic functions of archaevalue to possess the dual enzymatic functions of a cleaving DNA in a specific manner at a connection of the cleaving the cleaving the connection of the cleaving the
                                                                                                                                cleaving DNA in a specific recognition for recognition to recognition the specific recognition for recognition to recognition to recognition to recognition to recognition to recognition distance from their recognition commences to recognition to 
                                                                                                                                              distance trom the specific recognition sequences to protect the distance trom their recognition sequences arriviry and modifying from clearage by analogue and all modifying the sequence and all modified the sequence and all mo
                                                                                                                                                           modifying their recognition sequences to protect the endonuclease activity. An host DNA from cleavage by endonuclease his process to protect the activity. An endonuclease activity and process to protect the protect the endonuclease activity. An endonuclease activity and process to protect the endonuclease activity. An endonuclease activity and process to protect the endonuclease activity. An endonuclease activity and the endonuclease activity. An endonuclease activity and the endonuclease activity and the endonuclease activity.
                                                                                                                                                                               host DNA from cleavage by endonuclease activity. An is process is example of such an enzyme identified by this process.
                                                                                                                                                                                                                          concurrently nerewith). CetMI was identified as a ficant highly significant of its highly recommized because of its highly recommized potential endonuclease because of man recommized potential endonuclease aimilarity to man recommized anima anima
                                                                                                                                                                                                             CSEMIL (See U.S. Application Serial No.: identified as a concurrently herewith).
                                                                                                                                                                                               example of such an energine formation serial No.
                                                                                                                                                                                                                                           potential endonuclease pecause of its highly significant recognizes

potential endonuclease pecause of MmeI. CstMI recognizes

amino acid sequence similarity to MmeI.
                                                                                                                                                                                                                                                              amino acid sequence similarity to MmeI. CstMI recognizes

the sequence 5'-AAGGAG-3' and cleaves the phosphodiester

the sequence 5'-AAGGAG-3' and 21 ct - 20 c

Restriction endonucleases act by recognizing and binding to particular sequences of nucleotides (the 'recognition sequence') along the DNA molecule. Once bound, the type II endonucleases cleave the molecule within, or to one side of, the sequence. Different 5 restriction endonucleases have affinity for different recognition sequences. The majority of restriction endonucleases recognize sequences of 4 to 6 nucleotides in length, although recently a small number of restriction endonucleases which recognize 7 or 8 10 uniquely specified nucleotides have been isolated. Most recognition sequences contain a dyad axis of symmetry and in most cases all the nucleotides are uniquely specified. However, some restriction endonucleases have degenerate or relaxed specificities in that they 15 recognize multiple bases at one or more positions in their recognition sequence, and some restriction endonucleases recognize asymmetric sequences. HaeIII, which recognizes the sequence 5'-GGCC-3', is an example of a restriction endonuclease having a symmetrical, non-20 degenerate recognition sequence; HaeII, which recognizes 5'-(Pu)GCGC(Py)-3' typifies restriction endonucleases having a degenerate or relaxed recognition sequence; while BspMI, which recognizes 5'-ACCTGC-3' typifies restriction endonucleases having an asymmetric 25 recognition sequence. Type II endonucleases with symmetrical recognition sequences generally cleave symmetrically within or adjacent to the recognition site, while those that recognize asymmetric sequences tend to cleave at a distance of from 1 to 20 nucleotides 30 to one side of the recognition site. The enzyme of this application, MmeI, (along with CstMI) has the distinction of cleaving the DNA at the farthest distance from the recognition sequence of any known type II restriction endonuclease. More than two hundred unique 35

restriction endonucleases have been identified among several thousands of bacterial species that have been examined to date.

5 A second component of restriction systems are the modification methylases. These enzymes are complementary to restriction endonucleases and they provide the means by which bacteria are able to protect their own DNA and distinguish it from foreign, infecting Modification methylases recognize and bind to the 10 same nucleotide recognition sequence as the corresponding restriction endonuclease, but instead of breaking the DNA, they chemically modify one or other of the nucleotides within the sequence by the addition of a methyl group. Following methylation, the recognition 15 sequence is no longer cleaved by the restriction endonuclease. The DNA of a bacterial cell is modified by virtue of the activity of its modification methylase and it is therefore insensitive to the presence of the endogenous restriction endonuclease. It is only 20 unmodified, and therefore identifiably foreign, DNA that is sensitive to restriction endonuclease recognition and cleavage. Modification methyltransferases are usually separate enzymes from their cognate endonuclease partners. In some cases, there is a single polypeptide 25 that possesses both a modification methyltransferase function and an endonuclease function, for example, Eco57I. In such cases, there is a second methyltransferase present as part of the restrictionmodification system. In contrast, the MmeI system of the 30 present application has no second methyltransferase accompanying the endonuclease-methyltransferase polypeptide.

Endonucleases are named according to the bacteria from which they are derived. Thus, the species Haemophilus aegyptius, for example synthesizes 3 different restriction endonucleases, named HaeI, HaeII and HaeIII. These enzymes recognize and cleave the sequences 5'-(W)GGCC(W)-3', 5'-(Pu)GCGC(Py)-3' and 5'-GGCC-3' respectively. Escherichia coli RY13, on the other hand, synthesizes only one enzyme, EcoRI, which recognizes the sequence 5'-GAATTC-3'.

While not wishing to be bound by theory, it is thought that in nature, restriction endonucleases play a protective role in the welfare of the bacterial cell. They enable bacteria to resist infection by foreign DNA molecules such as viruses and plasmids that would otherwise destroy or parasitize them. They impart resistance by binding to infecting DNA molecules and cleaving them in each place that the recognition sequence occurs. The disintegration that results inactivates many of the infecting genes and renders the DNA susceptible to further degradation by exonucleases.

More than 3000 restriction endonucleases have been isolated from various bacterial strains. Of these, more than 240 recognize unique sequences, while the rest share common recognition specificities. Restriction endonucleases which recognize the same nucleotide sequence are termed "isoschizomers." Although the recognition sequences of isoschizomers are the same, they may vary with respect to site of cleavage (e.g., XmaI v. SmaI, Endow, et al., J. Mol. Biol. 112:521 (1977); Waalwijk, et al., Nucleic Acids Res. 5:3231 (1978)) and in cleavage rate at various sites (XhoI v. PaeR7I, Gingeras, et al., Proc. Natl. Acad. Sci. U.S.A.

80:402 (1983)).

which may also be involved in DNA recognition, a DNA modification domain most similar to the gamma-class N6mA methyltransferases, and a carboxy-terminal domain presumed to be involved in dimer formation and possibly DNA recognition. The enzyme requires SAM for both cleavage and modification activity. The single MmeI polypeptide is sufficient to modify the plasmid vector carrying the gene *in vivo* to provide protection against MmeI cleavage *in vitro*, yet it is also able to cleave unmodified DNAs *in vitro* when using the endonuclease buffer containing Mg++ and SAM.

There is a continuing need for novel type II restriction endonucleases. Although type II restriction endonucleases which recognize a number of specific nucleotide sequences are currently available, new restriction endonucleases which recognize novel sequences provide greater opportunities and ability for genetic manipulation. Each new unique endonuclease enables scientists to precisely cleave DNA at new positions within the DNA molecule, with all the opportunities this offers.

SUMMARY OF THE INVENTION

25

20

5

10

1.5

In accordance with the present invention, there is provided a novel DNA fragment encoding a novel restriction endonuclease, obtainable from *Methylophilus methylotrophus* (NEB#1190). The endonuclease is hereinafter referred to as "MmeI", which endonuclease:

(1) recognizes the degenerate nucleotide sequence
5'-TCC(Pu)AC-3' in a double-stranded DNA
molecule as shown below:

30

35

5'-TCC(Pu)AC-3' 3'-AGG(Py)TG-5'

(wherein G represents guanine, C represents
cytosine, A represents adenine, T represents
thymine, (Pu) represents a purine, either A or
G, and (Py) represents a pyrimidine, either C
or T);

(2) cleaves DNA in the phosphodiester bond following the 20th nucleotide 3' to the recognition sequence 5'-TCC(Pu)AC-3 and preceding the 18th nucleotide 5' to the complement strand of the recognition sequence 5'-GT(Py)GGA-3' to produce a 2 base 3' extension:

> 5'-TCC(Pu)AC(N20)/-3' 3'-AGG(Py)GT(N18)/-5'; and

(3) methylates the recognition sequence specified in (1) in vivo to protect the host DNA from cleavage by the MmeI endonuclease activity;

The invention further relates to additional DNA fragments, each of which is identified to encode polypeptides which share significant sequence similarity to the MmeI restriction-modification polypeptide. The DNA fragment encoding the MmeI polypeptide enables the identification of these additional potential endonucleases by using similarity searching of the MmeI sequence against sequences available in databases, such as GENBANK, using a program such as BLAST (Altschul, et al. Nucleic Acids Res. 25:3389-3402 (1997)). These DNA fragments, as well as any other fragments with such

10

15

20

25

30

35

similarity to MmeI that may be deposited in the databases in the future, are candidates which may encode polypeptides that are similar to MmeI, in that the polypeptides encoded act as both restriction endonuclease and methyltransferase. These polypeptides may, like MmeI, cleave DNA at a similarly far distance from the recognition sequence, in the range of 18 to 20 nucleotides or more, which character is unique and useful in certain molecular biology technologies. Specifically these polypeptides contain amino acid motifs common to N6mA DNA methyltransferases in the middle of the polypeptide, have a motif common to restriction endonucleases and located in the aminoterminal section of the polypeptides, consisting of the amino acids D/E(X8-X12)D/EXK, and have a region of several hundred amino acids following the conserved methyltransferase motifs which are significantly similar to this region of MmeI and are believed to serve as a dimerization and possibly a DNA sequence recognition domain. An example of such a polypeptide, CstMI, is presented. CstMI has been shown to recognize the 6 base pair asymmetric sequence 5'-AAGGAG-3' and to cleave the DNA in the same manner as MmeI; 5'-AAGGAGN20/N18-3'. The endonuclease encoded by these DNA fragments may be produced by the process used for MmeI, as described below.

The present invention further relates to a process for the production of the restriction endonuclease MmeI. This process comprises culturing a transformed host, such as *E. coli*, containing the DNA fragment encoding the MmeI restriction system polypeptide, collecting the cultured cells, obtaining a cell-free extract therefrom and separating and collecting the restriction endonuclease MmeI from the cell-free extract. The

-10-

present invention further relates to a process for the production of the restriction endonucleases encoded by the DNA sequences identified as homologous to MmeI. This process comprises culturing a transformed host, such as *E. coli*, containing the gene for these restriction systems, collecting the cultured cells, obtaining a cell-free extract therefrom and separating and collecting the restriction endonuclease from the cell-free extract.

DETAILED DESCRIPTION OF THE INVENTION

The recognition sequence and cleavage site of the endonuclease of the present invention were previously described (Boyd, Nucleic Acids Res. 14: 5255-5274 (1986)). However the MmeI enzyme proved difficult to produce from the native host, Methylophilus methylotrophus, due to very low yield of the enzyme and the relative difficulty of growing the M. methylotrophus host in large quantity. To overcome these limitations to producing MmeI, the present application describes the identification of the DNA sequence encoding the MmeI gene and the expression of this MmeI gene in a suitable host, in the present instance E. coli. This manipulation of the MmeI encoding DNA fragment results in both a significant increase in the amount of enzyme produced per gram of cells and a significant increase in ease of growth of large amounts of cells containing MmeI enzyme.

20

25

5

10

15

Several standard approaches typically employed by persons skilled in the art of cloning were applied to the task of cloning of MmeI without success. Specifically, the methylase selection approach (Wilson, et al., U.S. Patent No. 5,200,333) was attempted unsuccessfully. Several random libraries of M. methylotrophus DNA were constructed in E. coli and challenged by digesting with MmeI, but no MmeI methylase containing clones were obtained.

30

35

A second approach was also attempted but failed. In this approach, antibodies specific for N6mA were used to screen a library of random clones constructed in a lambda phage replacement vector. The approach was successful in obtaining methylase positive clones, but

all examined were found to express the methyltransferase of the second restriction system in *M. methylotrophus*, the MmeII methylase (recognition sequence 5'-GATC-3') rather than the desired MmeI methylase activity.

5

15

20

25

30

35

The successful approach to obtain the desired DNA fragment encoding the MmeI restriction system involved several steps. First a novel purification procedure was developed to purify the MmeI endonuclease peptide to homogeneity from M. methylotrophus. Once this ultra pure MmeI endonuclease polypeptide was successfully obtained in a significant amount, amino acid sequence from the amino terminus and from internal cyanogen-bromide degradation peptides was determined. Using the amino acid sequence obtained, degenerate DNA primers complementary to the DNA coding for the amino acid sequences were synthesized and used to PCR amplify a portion of the MmeI gene. The DNA sequence of this portion of the MmeI gene was determined. The entire MmeI endonuclease gene and surrounding DNA sequences were then obtained by applying the inverse PCR technique. A number of primers matching the DNA sequence obtained were designed, synthesized and used in combination with numerous different templates. The inverse PCR templates were produced by digesting M. methylotrophus genomic DNA with various restriction endonucleases and then ligating the cut M. methylotrophus DNA at low concentration to obtain circular molecules. The various primers were tried in combinations with the various templates to find primer-template combinations that produced a specific PCR amplification product. The products thus obtained were sequenced. Once the DNA sequence encoding the entire MmeI endonuclease gene was obtained, primers were designed to specifically amplify the gene from M. methylotrophus genomic DNA. The amplified gene was

accordance with the present invention. Therefore correct internal amino acid sequences determination, which enabled the cloning of the MmeI gene, depended on the novel purification method described in this application for the production of sufficiently pure MmeI in large enough quantity to determine cyanogen bromide internal fragment amino acid sequences, as performed in this Application.

10

5

In Example II we obtained MmeI by culturing a transformed host carrying the MmeI gene, such as *E. coli* ER2683 carrying pTBMmeI.1 and recovering the endonuclease from the cells. A sample of *E. coli* ER2683 carrying pTBMmeI.1 (NEB#1457) has been deposited under the terms and conditions of the Budapest Treaty with the American Type Culture Collection (ATCC) on July 3, 2002 and bears the Patent Accession No. PTA-4521.

20

15

For recovering the enzyme of the present invention *E. coli* carrying pTBMmeI.1 (NEB#1457) may be grown using any suitable technique. For example, *E. coli* carrying pTBMmeI.1 may be grown in Luria broth media containing 100µg/ml ampicillin and incubated aerobically at 37°C with aeration. Cells in the late logarithmic stage of growth are induced by adding 0.3mM IPTG, grown for an additional 4 hours, collected by centrifugation and either disrupted immediately or stored frozen at -70°C.

30

25

The MmeI enzyme can be isolated from *E. coli* carrying pTBMmeI.1 cells by conventional protein purification techniques. For example, cell paste is suspended in a buffer solution and treated by sonication, high pressure dispersion or enzymatic digestion to allow extraction of the endonuclease by the buffer solution. Intact cells and cellular debris are

35

then removed by centrifugation to produce a cell-free extract containing MmeI. The MmeI endonuclease, along with its corresponding intrinsic methylase activity, is then purified from the cell-free extract by ion-exchange chromatography, affinity chromatography, molecular sieve chromatography, or a combination of these methods to produce the endonuclease of the present invention.

The present invention also relates to methods for identifying additional DNA fragments, each of which encodes a polypeptide having significant amino acid sequence similarity to the MmeI polypeptide. The polypeptides encoded by these DNA fragments are predicted to perform similar functions to MmeI. Specifically, they are predicted to possess the dual enzymatic functions of cleaving DNA in a specific manner at a relatively far distance from the specific recognition sequence and also modifying their recognition sequences to protect the host DNA from cleavage by their endonuclease activity. Once the amino acid sequence of the MmeI endonuclease was determined as described in this application, sequences deposited in databases can be compared to this MmeI sequence to find those few sequences that are highly significantly similar to MmeI. This method is similar to that of U.S. Patent No.6,383,770 (Roberts, et al.), except that here we are searching for similarity to the MmeI endonuclease sequence, rather than searching for sequences that match a database of methyltransferase or endonuclease proteins and then examining any unidentified open reading frames next to potential methyltransferase open reading frames. Prior to identifying the MmeI amino acid sequence, the DNA sequences coding for proteins related to MmeI had not been included in the database of restriction and methyltransferase gene sequences utilized by Roberts, et al., supra since these sequences had not been linked to

any known endonuclease function. The method disclosed herein of identifying potential MmeI-like endonucleases is thus more specific than the method of U.S. Patent No. 6,383,770 (Roberts, et al.).

5

10

15

20

Similarity searching of the MmeI sequence against sequences available in databases, such as GENBANK, is accomplished using a program such as BLAST (Altschul, et al. Nucleic Acids Res. 25:3389-3402 (1997)). A sequence with an expectation value (E) score of less than $E=e^{-10}$ is considered a potential candidate endonuclease. Sequences that give expectation values that are much lower, such as less than $E=e^{-30}$ is to be considered as highly likely to be endonucleases like MmeI. Such candidate MmeI-like peptides are further examined to see if they conform to the domain architecture that MmeI exhibits. A true candidate will contain an endonuclease fold motif, usually of the form (D/E)X8-X12(D/E)XK in the amino-terminal portion of the peptide, (Aravind et al. Nucleic Acid Res. 28:3417-3432 (2000)). A true candidate will contain methyltransferase motifs in the middle portion of the peptide similar to gamma class N6methyl adenine methyltransferases, and sequences similar to the carboxyl portion of MmeI in the carboxyl portion of the candidate peptide. Such a BLAST search performed on June 12, 2003 returned the following sequences as highly significantly similar to MmeI:

35

Most of these proteins are labeled as hypothetical or putative in their database entries. A number of these appear to be full-length polypeptides, such as sequence #2 above: GcrY. Such candidates can be expressed as described in Roberts to identify the expected endonuclease activity. Some endonuclease genes may be inactive in the particular strain used for sequencing (Lin, et al. Proc. Natl. Acad. Sci. USA 98:2740-2745 (2001)). In such a circumstance it may prove possible to express functional endonucleases by repairing the mutations that have inactivated these genes. Several of the MmeI homologs, such as #7 (SEQ ID NO:14) (Deinococcus radiodurans DR2267) and #8 (SEQ ID NO:13) (Deinococcus radiodurans DR0119.1) have disruptions in the open reading frames. DR2267 has a stop codon, TAG, which prematurely terminates the open reading frame, in a position where MmeI has a glutamate amino acid coded for by the codon GAG. By changing this TAG stop codon to GAG it may be possible to reactivate this potential endonuclease gene. DR0119.1 is also disrupted, in that it has a frameshift that disrupts open reading frame. The MmeI sequence may be used as a guide to direct where to repair this frameshift by maximizing the similarity of the DR0119.1 sequence to the MmeI sequence. This may well restore DR0119.1 endonuclease activity.

An alternative way to generate potential new endonucleases is to take advantage of their similar domain structure by performing domain swapping. One may be able to swap the amino terminal domain of an MmeI-like peptide, for the amino terminal domain in the MmeI protein, for example by swapping the sequence of the potential new gene up to the first methyltransferase motif (motif X, "Gly Ala His Tyr Thr Ser" into MmeI to replace this portion of MmeI up to the same sequence.

Docket No.: NEB-207-US

5

10

15

20

25

30

This approach may be particularly useful when only a partial sequence is available or a potential gene has lost function due to multiple mutations. This approach will create a chimeric protein that potentially has endonuclease activity and cleaves at a distance away from the recognition sequence, like MmeI, but that recognizes a novel DNA sequence. One may also find sequences in the databases that are highly similar to MmeI but that are partial. For example, sequence #11 (SEQ ID NO:9) above (Pseudomonas fluorescens) is from a small fragment of DNA sequence in the database. To obtain a functional endonuclease like MmeI from this sequence one can use inverse PCR or other techniques to obtain DNA sequence adjacent to the fragment reported, then use that sequence to obtain an intact endonuclease gene.

Once a sequence is identified the potential endonuclease can be expressed and characterized as described in Roberts, et al. supra. Here, however, there is no separate methyltransferase gene to express along with the endonuclease. Once such a potential endonuclease is cloned and expressed in a suitable host, such as in E. coli, a cell free extract is prepared and analyzed to detect any endonuclease activity. Such an endonuclease assay must include the SAM cofactor required by these endonucleases. Once specific DNA cleavage activity is found the recognition sequence and cleavage site may be determined by standard methods. (Schildkraut, (1984) In Genet. Eng. (N Y) Vol 6. (Setlow J.K., Hollaender, A. Ed.). pp 117-140. Plenum Press, New York. "Screening for and characterizing restriction endonucleases.")

10

15

20

25

30

35

The enzymes so identified can be isolated from E. coli cells carrying the DNA fragment in a suitable vector by conventional protein purification techniques. For example, cell paste is suspended in a buffer solution and treated by sonication, high pressure dispersion or enzymatic digestion to allow extraction of the endonuclease by the buffer solution. Intact cells and cellular debris are then removed by centrifugation to produce a cell-free extract containing the enzyme. The endonuclease, along with its corresponding intrinsic methylase activity, is then purified from the cell-free extract by ion-exchange chromatography, affinity chromatography, molecular sieve chromatography, or a combination of these methods to produce the endonuclease of the present invention.

These DNA fragments, as well as any other fragments with such similarity to MmeI that may be deposited in the databases in the future, are predicted to encode polypeptides that are similar to MmeI, in that the polypeptides encoded act as both restriction endonuclease and methyltransferase. These polypeptides may, like MmeI, cleave DNA at a similarly far distance from the recognition sequence, in the range of about 18 to 20 nucleotides or more, which character is unique and useful in certain molecular biology technologies.

An example of such an enzyme identified by this process is CstMI (see U.S. Application Serial No._____, filed concurrently herewith). CstMI was identified as a potential endonuclease because of its highly significant amino acid sequence similarity to MmeI. CstMI is encoded by sequence #2 above (SEQ ID NO:8), which gave highly significant Expectation value of e⁻¹⁷¹ when compared to MmeI by BLAST. CstMI recognizes

-22-

the 6 base pair asymmetric sequence 5'-AAGGAG-3' and cleaves the DNA in the same manner as MmeI: it cleaves the phosphodiester bond between the 20th and 21st residues 3' to this recognition sequence on this DNA strand, and between the 18th and 19th residues 5' to the recognition sequence on the complement strand 5'-CTCCTT-3' to produce a 2 base 3' extension.

The present invention is further illustrated by the following Examples. These Examples are provided to aid in the understanding of the invention and are not construed as a limitation thereof.

The references cited above and below are herein incorporated by reference.

EXAMPLE I

PURIFICATION OF MmeI ENDONUCLEASE

20

15

5

10

A single colony of Methylophilus methylotrophus (NEB#1190) was grown for 24 hrs in 1 liter of medium M (0.08 μM CuSO4, 0.448 μM MnSO4, 0.348 μM ZnSO4, 6.0 μM FeCl3, 18 μM CaCO3, 1.6 mM MgSO4, 9.0 mM NaH2PO4, 10.9 mM K2HPO4, 13.6 mM (NH4)2SO4) for 24 hours. This culture was used to inoculate 100 liters of medium M. The cells were grown aerobically at 37°C, overnight, until stationary. Five 100-liter fermentations were required to harvest 752 grams of wet cell pellet.

30

25

750 gram of *M. methylotrophus* cell pellet was suspended in 2.25 liters of Buffer A (20 mM Tris-HCl (pH 8.0), 50 mM NaCl, 1.0 mM DTT, 0.1 mM EDTA, 5% Gycerol) and passed through a Gaulin homogenizer at ~12,000 psig.

-23-

The lysate was centrifuged at $\sim 13,000 \times G$ for 40 minutes and the supernatant collected.

5

The supernatant solution was applied to a 500 ml Heparin Hyper-D column (BioSepra SA) which had been equilibrated in buffer A. A 1.0 L wash of buffer A was applied, then a 2 L gradient of NaCl from 0.05 M to 1 M in buffer A was applied and fractions were collected. Fractions were assayed for Mme I endonuclease activity by incubating with 1 μ g Lambda DNA (NEB) in 50 μ l NEBuffer 1, supplemented with 32 μ M S-adenosyl-L-methionine (SAM) for 15 minutes at 37° C. MmeI activity eluted at 0.3 M to 0.4 M NaCl.

15

10

The Heparin Hyper-D column fractions containing the Mme I activity were pooled, diluted to 50 mM NaCl with buffer A (without NaCl) and applied to a 105 ml Source15 Q column (Amersham Biotech) which had been equilibrated with buffer A. A 210 ml wash with buffer A was applied followed by a 1.0 L gradient of NaCl from 0.05 M to 0.7 M in buffer A. Fractions were collected and assayed from Mme I endonuclease activity. The Mme I activity was found in the unbound fraction.

25

20

The Source15 Q pool was loaded onto a 22 ml AF-Heparin-TSK column (TosoHaas) which had been equilibrated with buffer A. A wash of 44 ml buffer A was applied, followed by a linear gradient of NaCl from 0.05 M to 1.0 M in buffer A. Fractions were collected and assayed from Mme I endonuclease activity. The Mme I activity eluted between 0.26 M and 0.29 M NaCl. The fractions containing activity were pooled and dialyzed against buffer B (20 mM NaPO₄ (pH 7.0), 50 mM NaCl, 1.0 mM DTT, 0.1 mM EDTA, 5% Glycerol).

30

10

15

20

25

30

35

The dialyzed AF-Heparin-TSK pool was loaded onto a 6 ml Resource15 S column (Amersham Biotech) which had been equilibrated with buffer B. A wash of 12 ml buffer B was applied, followed by a linear gradient of NaCl from 0.05 M to 1.0 M in buffer B. Fractions were collected and assayed for Mme I endonuclease activity. Mme I activity eluted between 0.14 M and 0.17 M NaCl.

This pool was applied to a 2 liter Superdex 75 sizing column (Amersham Biotech) which had been equilibrated with buffer C (20 mM Tris-HCl, pH 8.0, 500 mM NaCl, 1.0 mM DTT, 0.1 mM EDTA, 5% Glycerol). Fractions were collected between 500 and 1500 ml elution with buffer C, then assayed by Mme endonuclease assay and polyacrylamide gel electrophoresis on 4-20% gradient gel, followed by protein staining with Coomassie Brilliant Blue dye. Fractions eluting between 775 and 825 ml corresponded to Mme I activity and a protein band of 105 kDa. These fractions were pooled and dialyzed against buffer D (20 mM NaPO₄ (pH 7.0), 50 mM NaCl, 1 mM DTT, 5% Glycerol).

The dialyzed sizing pool was applied to a 16 ml Ceramic HTP column (BioRad) which had been equilibrated with buffer D. A 32 ml wash with buffer D was followed by a linear gradient from 0.02 M to 1.0 M NaPO4 in buffer D. Fractions were collected and assayed by Mme endonuclease assay and polyacrylamide gel electrophoresis on a 4-20% gradient gel, followed by protein staining with Coomassie Brilliant Blue dye. Mme I eluted between 0.26 M and 0.3 M NaPO4. A portion of several fractions containing a single homogeneous protein band of 105 kDa were used for protein sequencing. The rest of the purified MmeI fractions were pooled (6 ml @ .36 mg/ml) and dialyzed against storage

-25-

buffer (10 mM Tris (pH 7.9), 50 mM KCl, 1mM DTT, .1 mM EDTA, 50% glycerol). The purified MmeI enzyme was stored at -20°C.

5 Activity determination:

Samples from 1-4 μ l were added to 50 μ l substrate solution consisting of 1X NEBuffer 1, 32 μ M S-adenosyl-L-methionine, and 1 μ g DNA (lambda, PhiX174 or pUC19 DNAs). Reactions were incubated for 15 minutes at 37°, received 20 μ l stop solution and were analyzed by electrophoresis on a 1% agarose gel.

Optimized endonuclease activity

15

20

25

30

35

10

Following purification of MmeI from M.

methylotrophus, experiments were performed to determine
the optimal reaction conditions for DNA cleavage.

Endonuclease activity was found to be significantly
enhanced by the presence of potassium in the reaction
buffer. Reactions were performed at 4°C to 37°C and from
5 to 60 minutes with no appreciable change in the amount
of DNA cleavage. Enzyme concentrations at or near
stoichiometric equivalence to DNA sites were required
for maximal cleavage. Large excess of enzyme blocked
cleavage. These findings were used to reassess the
activity of MmeI and to define a workable endonuclease
unit.

Unit definition

One unit of MmeI is defined as the amount of MmeI required to completely cleave 1 μg of PhiX174 DNA in 15 minutes at 37°C in NEBuffer 4 (20 mM Tris-acetate, 10 mM magnesium acetate, 50 mM potassium acetate, 1 mM

-26-

dithiothreitol (pH7.9 at 25°C)) supplemented with $80\mu\text{M}$ S-adenosyl-L-methionine (SAM).

EXAMPLE II

5

CLONING THE Mmel ENDONUCLEASE

- DNA purification: Total genomic DNA of Methylophilus methylotrophus was prepared. 5 grams of cell paste was suspended in 20 ml of 25% sucrose, 0.05 M 10 Tris-HCl pH 8.0, to which was added 10 ml of 0.25 M EDTA, pH 8.0. Then 6 ml of lysozyme solution (10 mg/ml lysozyme in 0.25 M Tris-HCl, pH 8.0) was added and the cell suspension was incubated at 4°C for 16 hours. ml of Lytic mix (1% Triton-X100, 0.05 M Tris, 62 mM 15 EDTA, pH 8.0) and 5 ml of 10% SDS was then added and the solution incubated at 37°C for 5 minutes. The solution was extracted with one volume of equilibrated phenol:chloroform:isoamyl alcohol (50:48:2, v/v/v) and the aqueous phase was recovered and extracted with one 20 volume of chloroform:isoamyl alcohol (24:1, v/v) two The aqueous solution was then dialysed against four changes of 2 L of 10 mM Tris, 1 mM EDTA, pH 8.0. The dialysed DNA solution was digested with RNase (100 μ g/ml) at 37°C for 1 hour. The DNA was precipitated by 25 the addition of 1/10th volume 5 M NaCl and 0.55 volumes of 2-propanol and spooled on a glass rod. The DNA was briefly rinsed in 70% ethanol, briefly air dried and dissolved in 20 ml TE (10 mM Tris, 1 mM EDTA, pH 8.0) to a concentration of approximately 500 $\mu\text{g/ml}$ and stored at 30 4°C.
 - 2. The MmeI endonuclease was purified to homogeneity as described in Example I above.

10

15

Amino acid sequences of the MmeI endonuclease were obtained for the amino terminus and for several internal cyanogen bromide digestion products of the MmeI polypeptide. The MmeI restriction endonuclease, prepared as described in Example I above, was subjected to electrophoresis and electroblotted according to the procedure of Matsudaira (Matsudaira. J. Biol. Chem. 262:10035-10038, 1987)), with modifications as previously described (Looney, et al. Gene 80:193-208 (1989)). The membrane was stained with Coomassie blue R-250 and the protein band of approximately 105 kD was excised and subjected to sequential degradation on an ABI Procise 494 Protein/Peptide Sequencer with gas-phase delivery (Waite-Rees, et al. J. Bacteriol. 173:5207-5219 (1991)). The amino acid sequence of the first 14 amino terminal residues obtained was the following: ALSWNEIRRKAIEF (SEQ ID NO:15).

An additional sample of the MmeI endonuclease, 20 μg in 20 μl , was treated with 2 μg of cyanogen bromide 20 (Sigma) dissolved in 200 μ l of 88% distilled formic acid for 24 hours in the dark at room temperature. This reaction mixture was evaporated to dryness and resuspended in 20 μ l of loading buffer (1.5M Tris-HCl, pH 8.5, 12% glycerol, 4% SDS, 0.05% Serva Blue G, 0.05% 25 Phenol Red) at 100°C for 5 minutes. This sample was subjected to electrophoresis on a Tris-Tricine 10 to 20% polyacrylamide gradient gel (Invitrogen) for three hours and then transferred to a polyvinylidene difluoride (PVDF) membrane (Problott, Applied Biosystems Inc.) 30 using 10 mM CAPS buffer (10mM 3-[cyclohexylamino]-1propanesulfonic acid, 10% methanol, 0.05% SDS, 0.005% dithiotheritiol, adjusted to pH 11.0 with NaOH) for 18 hours at 200 volts in a tank electroblotter (TE52, Hoeffer). The membrane was stained with Coomassie blue 35

10

15

35

R-250 and major bands of 25 kilodaltons (kD), 14 kD, 7.5 kD and 6 kD were observed, as well as smaller bands. These stained protein bands were excised from the membrane and each subjected to sequential degradation. The fragments other than the amino terminal fragment are derived from internal cleavage by cyanogen bromide at methionine residues from within the protein and thus should be preceded by a methionine. The first 29 residues of the 25 kD peptide corresponded to (M) KISDEFGNYFARIPLKSTXXIXEXNALQ (SEQ ID NO:16). Residues 20, 21, 23 and 25, labeled X, were not identified. The first 40 amino acid residues obtained from the 14kD fragment were: (M) DAKKRRNLGAHYTSEANILKLI KPLLLDELWVVFXKVKN (SEQ ID NO:17). Residue 36 was not determined. The first 25 residues of the 7.5 kD peptide corresponded to (M) KSRGKDLDKAYDQALDYFSGIAER (SEQ ID NO:18). The 6kD fragment was found to contain a mixture of three sequences.

- 20
 4. Amplification of a portion of the MmeI endonuclease: The peptide sequence data from the amino terminus, 25 kD, 14kD and 7.5kD peptides was used to construct a series of degenerate PCR primers corresponding to the codons for the amino acid residues.

 The order of the internal peptide fragments was unknown, so both forward (sense strand) and reverse (antisense strand) primers were made for these fragments. The primers were:
- 30 **25 kD fragment**: residues DEFGNYFA (SEQ ID NO:19) Forward:
 - 1) 5'-GARTTYGGNAAYTAYTTYGC-3' (SEQ ID NO:20)
 Reverse:

25 where

30

45

Y = T, C

R = A,G

H = A, T, C

S = G, C

N = A, C, G, T

CNBr peptide and were prepared to prime on the sense strand (1) or the antisense strand (2) of the gene.

Primers 3 through 5 are derived from the 14 kD CNBr peptide and were prepared to prime on the sense strand (3 and 4) or the antisense strand (5) of the gene, with 3 and 4 differing in the codon usage for the arginine residue. Primers 6 and 7 are derived from the 7.5 kD CNBr peptide and were prepared to prime on the sense strand (6) or the antisense strand (7) of the gene.

PCR amplification reactions were performed using the primer combinations of 1 with 5, 1 with 7, 3 with 2,

-30-

3 with 7, 4 with 2, 4 with 7, 6 with 2 and 6 with 7. A portion of the MmeI gene was amplified in a PCR reaction by combining:

5 80 μ l 10X Thermopol buffer (NEB) 50 μ l 4mM dNTP solution (NEB) 4 μ l MmeI genomic DNA (500 μ g/ml stock) 16 μ l 100mM MgSO₄ 586 μ l dH₂O 10 16 μ l (32 units) Vent® exo- DNA polymerase (NEB).

This master mix was divided into 8 aliquots of 90 μ l, to which was added 5 μ l forward primer (10 μ M stock) and 5 μ l reverse primer (10 μ M stock). The cycling

parameters were 95°C for 3 minutes for one cycle, then 95°C for 30 seconds, 46°C for 30 seconds, 72°C for 2

minutes, for 25 cycles.

The amplification reactions were electrophoresed on a 1% agarose gel and analyzed. Major DNA amplification products of 450 base pairs (bp) (primers 2 with 4), 650 bp (primers 5 with 6) and 1100 bp (primers 2 with 6) were obtained. These fragment sizes are consistent with the 7.5 kD CnBr fragment being located nearest the amino end of the protein and approximately 650 bp away from the 14kD CnBr fragment, with the 14 kD fragment between the 7.5 kD and the 25 kD fragment and adjacent to the 25 kD fragment. The amplified DNA fragments were gel purified and sequenced using the primers that were used for the amplification. A translation of the DNA sequence obtained matched the amino acid sequence derived from the purified MmeI endonuclease, indicating that a portion of the MmeI endonuclease gene DNA sequence had been successfully obtained.

30

15

20

25

-31-

5. Determining the DNA sequence for the entire MmeI gene and adjacent DNA: The inverse PCR technique was used to extend the DNA sequence from both sides of the 1060 bp of the MmeI gene obtained above. To accomplish this a series of primers matching the MmeI gene DNA sequence and oriented for inverse PCR were designed and synthesized. MmeI genomic DNA was cut with a number of restriction endonucleases and ligated at low concentration to generate circular DNA templates.

10

5

A. MmeI genomic DNA was digested with ten different restriction endonucleases and then circularly ligated to obtain DNA templates to amplify using the inverse PCR technique. The restriction enzymes used were:

15

BspHI (T/CATGA)

ECORI (G/AATTC)

HindIII (A/AGCTT)

HinP1I (G/CGC)

20 MspI (C/CGG)

NlaIII (CATG/)

PstI (CTGCA/G)

SacI (GAGCT/C)

SphI (GCATG/C)

25 XbaI (T/CTAGA)

Restriction enzyme digests were performed by combining:

30

5 μ l 10X NEBuffer recommended for the enzyme (varied with enzyme)

2 μ 1 M. methyloptrophus genomic DNA (1 μ g)

43 μ 1 dH₂0

1 μ 1 (10 - 20 units) restriction enzyme.

35

The reactions were incubated for 1 hour at 37°C . The restriction endonuclease was inactivated by heating

-32-

the reaction to 65°C (80°C for PstI) for 20 minutes. The digested DNA was then ligated into circular fragments by adding 50 μl 10% T4 DNA ligase buffer, 400 μl dH₂O and 3 μl concentrated T4 DNA ligase (6000 units, New England Biolabs, Inc.) and incubating at 16°C for 16 hours. The ligated DNA was then extracted with phenol and chloroform, precipitated with 2-propanol and resuspended in 100 μl TE buffer.

10

5

B. Amplification of DNA adjacent to the 1060 bp fragment of the MmeI endonuclease gene: Two pairs of PCR primers were designed, one near each end of the 1060 bp sequence obtained from direct PCR with degenerate primers. The primer sequences were:

15

primer IP 1:

5'-GTTGGATCCCGCACAGATTGCTCAGG-3' (SEQ ID NO:29)

20

primer IP 2:

5'-GTTGGATCCTACGTTAATCTGAATAAGATG-3' (SEQ ID NO:30)

primer IP 3:

25

5'-GTTGGATCCTGTTAATCTGAAACGCTGG-3' (SEQ ID NO:31)

primer IP 4:

30

35

5'-GTTGGATCCTTATACCAAAATGTGAGGTC-3' (SEQ ID NO:32)

Inverse PCR reactions were performed on the 10 circularized templates produced above with the primer pairs of IP 1 with IP 2, IP 3 with IP 4, and IP 1 with IP 3. The amplification reactions were assembled by combining:

- 80 µl 10X Thermopol buffer (NEB)
- $50 \mu l 4mM dNTP solution (NEB)$
- 40 μl IP primer (forward)

-33-

 μl IP primer (reverse) μl 100mM MgSO4 μl dH2O μl (32 units) Vent® exo- DNA polymerase (NEB).

10

The master mix was aliquoted into ten tubes of 76 μ l, to which was added 4 μ l of the appropriate digested, circularly ligated template. The cycling parameters were 95°C for 3 minutes for one cycle, then 95°C for 30 seconds, 56°C for 30 seconds, 72°C for 3 minutes, for 25 cycles. Amplification products were analyzed by agarose gel electrophoresis.

For primers IP 1 and IP 2 with the SphI template and the NlaIII template a product of approximately 825 15 bp was obtained. For primers IP 3 and IP 4 with the BspHI template a product of approximately 800 bp was obtained. For primers IP 1 and IP 3 with the EcoRI template a product of approximately 1500 bp was obtained. These amplified DNA fragments were gel 20 purified, sequenced and assembled with that previously obtained. The assembled sequence did not contain the entire MmeI endonuclease open reading frame. The assembled sequence was used to direct synthesis of a second group of inverse PCR primer pairs. The sequences 25 of these primers were:

primer IP 5:

30 5'-TTCAGAAATACGAGCGATGC-3'(SEQ ID NO:33)

primer IP 6:

35 5'-GTCAAGCCATAAACACCATC-3'(SEQ ID NO:34)

primer IP 7:

40 5'-GAGGGTCAGAAAGGAAGCTG-3'(SEQ ID NO:35)

primer IP 8:

5'-GTCCAACTAACCCTTTATGG-3'(SEQ ID NO:36)

5

10

15

20

Inverse PCR amplification reactions were performed as above. Using primers IP 5 and IP 6, products were obtained from the NlaIII template (approximately 450 bp) and the MspI template (approximately 725 bp), but not from the other circular ligation templates. Using primers IP 7 and IP 8, products were obtained from the EcoRI template (approximately 500 bp), the SphI template (approximately 825 bp) and the BspHI template (approximately 750 bp). These DNA fragments were sequenced and the sequence was assembled with that previously obtained. The assembled sequence did not yet contain the entire MmeI endonuclease open reading frame, so another round of primer synthesis and inverse PCR was performed. Additional DNA templates were generated as above, but using the restriction enzymes Apol (R/AATTY), AseI (AT/TAAT), BsaHI (GR/CGYC), MfeI (C/AATTG), SspI (AAT/ATT) and EcoRV (GAT/ATC) to digest M. methylotrophus genomic DNA. The sequences of this third round of primers were:

25

35

primer IP 9:

5'-TTCCTAGTGCTGAACCTTTG-3' (SEQ ID NO:37)

30 primer IP 10:

5'-GTTGCGTTACTTGAAATGAC-3' (SEQ ID NO:38)

primer IP 11:

5'-CCAAAATGGAACTTGTTTCG-3' (SEQ ID NO:39)

primer IP 12:

40 5'-GTGAGTGCGCCCTGAATTAG-3' (SEQ ID NO:40)

-35-

Inverse PCR amplification reactions were performed as above. Using primers IP 9 and IP 10, products were obtained from the NlaIII template (approximately 425 bp), the MfeI template (approximately 750 bp), the ApoI template (approximately 800 bp) and the MspI template (approximately 2100 bp). Using primers IP 11 and IP 12, products were obtained from the SphI template (approximately 875 bp), the BspHI template (approximately 925 bp) and the EcoRI template (approximately 950 bp). These DNA fragments were sequenced and the sequence was assembled with the sequences previously obtained. Further sequencing was performed on the IP 9, IP10 MspI 2100 bp product using three additional primers:

primer S1:

5'-GCTTCATTTCATCCTCTGTGC-3' (SEQ ID NO:41)

20

5

10

15

primer S2:

5'-TAACCGCCAAAATTAATCGTG-3' (SEQ ID NO:42)

primer S3:

25

30

35

5'-CCACTATTCATTACAACACC-3' (SEQ ID NO:43)

The final assembled sequence (Figure 2) contained the entire MmeI restriction gene, as well as 1640 bp of sequence preceding the gene and 1610 bp of sequence following the gene.

6. Cloning the MmeI endonuclease gene in E. coli: The putative MmeI endonuclease open reading frame was identified from the DNA sequence assembly obtained

5

10

15

20

25

30

from sequencing the various inverse PCR amplified DNA fragments. The beginning of the open reading frame was identified on the basis of the match of the predicted amino acid sequence at the amino terminus of the open reading frame with the sequence determined from the MmeI endonuclease protein. The predicted end of the open reading frame would allow for the coding of an approximately 105 kD polypeptide, which matched the observed size of the native MmeI endonuclease. The amino acid sequence deduced from translation of this open reading frame contained conserved sequence motifs of N6mA DNA methyltransferases. However, no open reading frame containing sequence motifs conserved among DNA methyltransferases was observed adjacent to the MmeI endonuclease gene, as had been expected. It was decided to try to express the MmeI endonuclease in E. coli without having a second methyltransferase present to protect the E. coli host DNA from cleavage. Oligonucleotide primers were synthesized to specifically amplify the MmeI gene from M. methylotrophus genomic DNA for expression in the cloning vector pRRS (Skoglund, Gene 88:1-5 (1990)). The forward primer contained a PstI site for cloning, a stop codon in frame with the lacZ gene of the vector, a consensus E. coli ribosome binding site, the ATG start codon for translation (changed from the GTG used by M. methylotrophus to facilitate greater expression in E. coli) and 20 nucleotides that matched the M. methylotrophus DNA sequence:

5'-GTTCTGCAGTTAAGGATAACATATGGCTTTAAGCTGGAACGAG-3'
(SEQ ID NO:44)

The reverse primer contained a BamHI site for cloning and 22 nucleotides that matched the M.

-37-

methylotrophus DNA sequence 3' to the end of the MmeI open reading frame:

5'-GTTGGATCCGTCGACATTAATTAATTTTTGCCCTTAG-3'
(SEO ID NO:45)

The MmeI gene was amplified in a PCR reaction by combining:

10 50 μl 10X Thermopol buffer (NEB)

30 μ l 4mM dNTP solution

12.5 µl forward primer (10µM stock)

12.5 µl reverse primer (10µM stock)

5 μl MmeI genomic DNA (500μg/ml stock)

15 387 μ 1 dH₂O

5

20

25

30

3 µl (6 units) Vent® DNA polymerase

The reaction was mixed and aliquoted into 5 tubes of 80 µl each. MgSO₄ was added (100mM stock) to bring the final concentration of Mg++ ions to 2mM, 3mM, 4mM, 5mM and 6mM respectively. The cycling parameters were 95°C for 30 seconds, 60°C for 30 seconds, 72°C for 3 minutes, for 24 cycles. The reactions were analyzed by gel electrophoresis and the 3mM through 6mM Mg++ reactions were found to contain a DNA band of the desired size of 2.8kb. These reactions were pooled and the 2.8kb band was gel purified. The 2.8kb amplified MmeI gene fragment was digested with BamHI and PstI endonucleases (NEB) in the following reaction conditions:

15 μ l 10X BamHI reaction buffer (NEB)

1.5 μ l BSA (NEB)

50 µl MmeI gene 2.8 kb amplified DNA fragment

35 80 μ 1 dH20

10

15

20

25

30

35

5 μl BamHI endonuclease (100 units)

5 μl PstI endonuclease (100 units)

The reaction was mixed and incubated for 1 hour at 37°C. The small fragments cleaved off the ends of the 2.8kb DNA fragment were removed, along with the endonucleases, by purification on a Qiagen QiaPrep spin column according to the manufacturer's instructions.

The cleaved MmeI gene DNA fragment was ligated to the pRRS vector as follows: 10 μ l of the digested, purified 2.8kb MmeI fragment was combined with 5 µl pRRS vector previously cleaved with BamHI and PstI and purified, 5 µl dH,O, 20 µl 2X QuickLigase Buffer (NEB), the reaction was mixed, and 2 μl of QuickLigase was added. The reaction was incubated at room temperature for 5 minutes. 5 μ l of the ligation reaction was transformed into 50 μ l chemical competent *E. coli* ER2683 cells and the cells were plated on L-broth plates containing 100 $\mu g/ml$ ampicillin and incubated at 37°C overnight. Approximately 200 transformants were obtained and 18 representatives were analyzed as follows: plasmid from each colony was isolated by miniprep procedures and digested with AlwNI and NdeI endonucleases to determine if they contained the correct size insert. 2 of the 18 transformants had the correct size insert of approximately 2800 bp. Both clones were tested to see if they produced MmeI endonuclease activity. The clones were grown overnight at 37°C in 500 mL L-broth containing 100 µg/ml ampicillin. The cells were harvested by centrifugation, suspended in 10 mL sonication buffer (20mM Tris-HCl, 1mM DTT, 0.1mM EDTA, pH7.5) and broken by sonication. The crude lysate was cleared by centrifugation and the supernatant was recovered. The lysate was assayed for endonuclease

10

15

20

25

30

-39-

activity by serial dilution of the lysate in 1X reaction buffer NEBuffer 1 (New England Biolabs) containing 20 µg/ml lambda DNA substrate and supplemented with SAM at 100 µM final concentration. The reactions were incubated for 1 hour at 37°C. The reaction products were analyzed by agarose gel electrophoresis on a 1% agarose gel in 1X TBE buffer. One of the two clones had MmeI endonuclease activity. This active clone was designated strain NEB1457 and was used for subsequent production of MmeI. The plasmid construct expressing MmeI activity in this clone was designated pTBMmeI.1.

EXAMPLE III

THE Mmei ENDONUCLEASE PROVIDES IN VIVO PROTECTION AGAINST MMEI CLEAVAGE

The plasmid pTBMmeI.1 was purified from NEB1457 using the Qiagen miniprep protocol. This plasmid has two MmeI sites in the vector backbone, and one site within the MmeI gene. The plasmid was digested with MmeI to test whether this DNA was resistant to MmeI endonuclease activity, which would indicate that the single MmeI gene was able to methylate DNA in vivo to protect the host DNA against its endonuclease activity. To test this the following were combined:

10 µl pTBMmeI.1 miniprep DNA
15 µl 10X NEBuffer 4
15 µl SAM (1mM stock solution)
110 µl dH2O
1 µl MmeI endonuclease (15 units)

The reaction was mixed and split in thirds. To one third was added 0.5 μl dH₂O, to the second was added 0.5 μl pRRS vector and to the third was added 0.5 μl PhiX174

-40-

DNA as a positive control. The pTBMmeI.1 was not cleaved by the MmeI endonuclease activity, while the Phix174 and pRRS DNAs in the same reaction were cleaved, indicating that the three MmeI sites in the pTBMmeI.1 DNA are resistant to MmeI endonuclease activity (Figure 4).

EXAMPLE IV

MmeI ENDONUCLEASE SENSITIVITY TO METHYLATION

10

15

20

5

The prior literature reports that MmeI endonuclease methylates just one strand of its recognition sequence, and that this hemi-methylation does not block subsequent cleavage of the DNA by the endonuclease (Tucholski, Gene 223 (1998) 293-302). To test this a set of four oligonucleotides were synthesized so that a DNA substrate could be formed that was either unmethylated (oligo 1 + oligo 2), methylated in the top strand only (oligo 3 + oligo 2), methylated in the bottom strand only (oligo 1 + oligo 4), or methylated on both strands (oligo 3 + oligo 4). The oligos synthesized were:

Oligo 1:

25

5'-FAM-GTTTGAAGACTCCGACGCGATGGCCAGCGATCGGCGCCTCAGCTTT TG-3' (SEQ ID NO:46)

Oligo 2:

30

5'-FAM-CAAAAGCTGAGGCGCCGATCGCTGGCCATCGCGTCGGAGTCTTCA
AAC-3' (SEQ ID NO:47)

Oligo 3:

35

5'-FAM-GTTTGAAGACTCCG(6mA)CGCGATGGCCAGCGATCGGCGCCTCAGCTT TTG-3' (SEQ ID NO:48) Oligo 4:

5

10

15

20

25

30

35

5'-FAM-CAAAAGCTGAGGCGCCGATCGCTGGCCATCGCGTCGG (6mA)GTCTTCA
AAC-3' (SEQ ID NO:49)

(Other nucleotides outside the MmeI recognition sequence were also methylated for other studies, but since MmeI does not have any sequence specifity for these nucleotides this does affect MmeI activity and these other methylations are omitted here for clarity.) Duplex DNA was formed by mixing $100\mu l$ top strand oligo $(14\mu M \text{ stock})$ with $100\mu l$ bottom strand oligo $(14\mu M$ stock), heating to 85°C and cooling slowly to 30°C over a time of 20 minutes. MmeI was then used to cleave the oligo pairs in a 30 μ l reaction of 1X NEBuffer4, 2.5 μ M oligo, 100 μ M SAM and 2.5 units MmeI. As a control, restriction endonuclease Hpy188I was also used to cleave the oligo DNA. The Hpy188I recognition sequence overlaps the first 5 nucleotides of the MmeI recognition sequence in this DNA, 5'-TCNGA-3' and is blocked by methylation at the adenine in either strand of the DNA. MmeI was found to cleave unmethylated DNA as expected. In contrast to previous teaching (Tucholski, Gene 223:293-302 (1998)) MmeI did not cleave the hemi-methylated DNA when the top strand only was methylated: 5'-TCCG(N6mA)C-3'. When the bottom strand only was methylated MmeI did cleave the DNA. When both strands were methylated MmeI did not cleave the DNA. (Figure 5) This finding is consistent with both the observed ability of the single MmeI enzyme to protect host DNA against cleavage in vivo and the observation that MmeI methylates only the top strand of its recognition sequence. We confirmed the report that MmeI enzyme methylates only the top strand of its recognition sequence by methylating the oligo

-42-

pairs above with tritium labeled H³-SAM, washing away the unincorporated SAM and counting the radioactivity in the DNA. Both the unmethylated oligo DNA and the top unmethylated, bottom methylated DNAs had greater than 10-fold more counts than background, while the bottom unmethylated, top methylated DNA and the DNA with both strands methylated had counts near background (Figure 6). These findings indicate that MmeI is a novel type of restriction modification system which does not require a separate methyltransferase enzyme to modify the host DNA to provide protection against the activity of the endonuclease, as is the case for the type IIG (also called type IV) enzymes such as Eco57I.

15 EXAMPLE V

DNA SEQUENCING and ANALYSIS

DNA Sequencing: DNA sequencing was performed on double-stranded templates on an ABI 373 or ABI 377 automated sequencer. Amplified DNA fragments and individual clones were sequenced with primers synthesized as above or from universal primers located in the vector.

25

30

35

20
